Automation service

Continuous Integration (CI): Automates the code integration process, allowing developers to frequently merge their code changes into a shared repository. This helps in identifying and addressing issues early in the development cycle.

Continuous Deployment (CD): Automates the deployment process to ensure that code changes are automatically tested, built, and deployed to production or staging environments. It enables faster and more reliable releases.

Automation: DevOps services heavily rely on automation tools for infrastructure provisioning, configuration management, and deployment, reducing manual errors and speeding up processes.

Monitoring and Feedback: Constant monitoring of applications and infrastructure helps in identifying issues, performance bottlenecks, and areas for improvement. Feedback loops are crucial for making iterative enhancements.

Collaboration and Communication: Encourages close collaboration between development, operations, and other stakeholders by fostering a culture of shared responsibility and communication.

Scalability and Flexibility: DevOps practices aim to create scalable and flexible systems, allowing teams to adapt to changing requirements and scale resources efficiently.
